# Using Mplus To Do <br> Dynamic Structural Equation Modeling 

Bengt Muthén<br>Professor Emeritus, UCLA<br>Mplus: https://www.statmodel.com bmuthen@statmodel.com<br>Tihomir Asparouhov<br>Mplus

## Mplus Web Talks: No. 6

February 2023
We thank Ellen Hamaker and Loes Keijsers for helpful comments and guidance on data sets, and Thuy Nguyen and Noah Hastings for expert assistance.

## Outline

- Section 1: Introducing the example
- At-risk mood profiles related to depression in adolescents
- Section 2: How to handle varying (random) times of measurement
- Understanding the TINTERVAL option
- also useful for creating time manually
- Section 3: Descriptive analyses to understand the data
- TYPE = TWOLEVEL BASIC
- Histograms
- Section 4: TYPE = TWOLEVEL (RANDOM), regular twolevel analysis
- Estimating the intraclass correlation, random variance, random covariance

## Outline Continued

- Section 5: Two-Level Analysis Bringing Time Into the Model
- Univariate DSEM
- Model diagram, equations, Mplus input, plots
- Section 6: Two-level DSEM and RDSEM analysis
- Bivariate DSEM/RDSEM
- Section 7: Categorical outcome
- Section 8: Cross-classified analysis
- Looking for trends over time
- Section 9: How large do N and T have to be?
- Checklist
- Monte Carlo simulations
- Section 10: References

## Section 1 Introducing the Example

## Grumpy or Depressed Data

- Data from a study designed to detect at-risk mood profiles related to depression in adolescents
- ESM questionnaires measuring positive and negative affect in Dutch adolescents ages 12 to $16,63 \%$ girls
- Positive and negative affect are measured as an average of six 7-category items
- Tiredness is measured on a 7 -point scale
- $\mathrm{N}=240$, several measures per day for 7 days, Tuesday - Monday
- Covariates: Gender, SDQ (measure of childhood emotional problems)
- de Haan-Rietdijk, Voelkle, Keijsers, Hamaker (2017). Discrete- vs. continuous-time modeling of unequally spaced experience sampling method data. frontiers in Psychology

## Schedule of Measurements

- Participants filled out ESM questionnaires throughout the day, including during school hours
- Questionnaires delivered on the adolescents' own smartphones
- Eight measurements taken randomly in 3 blocks of time between 8 am and 10 pm
- A morning measurement between 8 am and 10 am
- Six measurements between 10 am and 8 pm
- An evening measurement between 8 pm and 10 pm

## Section 2 How to Handle Varying Times of Measurement

## Varying Times of Measurement: Understanding the TINTERVAL Option

- Times of measurement are not the same across people - data are misaligned with respect to time due to random measurement occasions
- Varying times of observation are common in longitudinal data but needs special attention in DSEM due to its use of lagged effects:
- The time distance between measurements at time $t-1$ and time $t$ needs to be the same across people
- This can be accomplished by inserting missing data to align time: The TINTERVAL option

## Hypothetical Case 1: Frequent Measurements

| Data row | Original data |  |  |  | Aligned data |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\underline{\text { ID }=1}$ |  | $\underline{\mathrm{ID}=2}$ |  | $\underline{\text { ID }=1}$ |  | $\underline{\text { ID }=2}$ |  |
|  | t | y | t | y | t | y | t | y |
| 1 | 9 | $y_{1,9}$ | 9 | $\mathrm{y}_{2,9}$ | 9 | $\mathrm{y}_{1,9}$ | 9 | y2, 9 |
| 2 | 10 | $\mathrm{y}_{1,10}$ | 11 | $\mathrm{y}_{2,11}$ | 10 | $\mathrm{y}_{1,10}$ | * | * |
| 3 | 11 | $\mathrm{y}_{1,11}$ | 12 | $\mathrm{y}_{2,12}$ | 11 | $\mathrm{y}_{1,11}$ | 11 | $\mathrm{y}_{2,11}$ |
| 4 | 13 | $\mathrm{y}_{1,13}$ |  |  | * | * | 12 | $\mathrm{y}_{2,12}$ |
| 5 |  |  |  |  | 13 | $\mathrm{y}_{1,13}$ | * | * |

- Insertion of missing data rows using a time interval of 1 is obtained by the VARIABLE command option TINTERVAL $=t(1)$; where $t$ is the name of the time variable (e.g. hour) in the data set
- Data row $=$ bin number $=$ time used in the analysis

## Hypothetical Case 2: Infrequent Measurements

- With infrequent measurements, time interval = 1 gives many missing data rows: Wider time interval needed

|  | Original data |  | Tinterval $=2$ |  |  | Aligned data |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Data row | t | y |  | Bin | Bin range |  |  |
| 1 | 9 | $\mathrm{y}_{9}$ | 1 | $9-10$ | 9 | $\mathrm{y}_{9}$ |  |
| 2 | 13 | $\mathrm{y}_{13}$ | 2 | $11-12$ | $*$ | $*$ |  |
| 3 | 16 | $\mathrm{y}_{16}$ | 3 | $13-14$ | 13 | $\mathrm{y}_{13}$ |  |
| 4 | 19 | $\mathrm{y}_{19}$ | 4 | $15-16$ | 16 | $\mathrm{y}_{16}$ |  |
| 5 | 21 | $\mathrm{y}_{21}$ | 5 | $17-18$ | $*$ | $*$ |  |
|  |  |  | 6 | $19-20$ | 19 | $\mathrm{y}_{19}$ |  |
|  |  |  | 7 | $21-22$ | 21 | $\mathrm{y}_{21}$ |  |

## Choosing Tinterval for the Grumpy or Depressed Data

- The total number of hours for the study is $24 \times 7=168$
- The smaller the time interval, the better the match to the data, but the more missing data inserted
- Time interval $=1$ gives $24 / 1=24$ time points per day. Maximum number of time points $=24 \times 7=168$. Coverage $=0.171$
- Time interval $=2$ gives $24 / 2=12$ time points per day. Maximum number of time points $=12 \times 7=84$. Coverage $=0.341$
- Time interval $=3$ gives $24 / 3=8$ time points per day which was the aim of the study. Maximum number of time points $=8 \times 7=$ 56. Coverage $=0.507$
- Coverage $=$ proportion not missing

## Tinterval Examples: ID = 41 with Interval 3 (3 Hours)

| Bin \# <br> (bin time) | Bin <br> range | Observed <br> time | Observed <br> time rearranged | New time mid <br> point of bin range |
| :--- | :--- | :--- | :--- | :--- |
| 1 | $0-2$ | $*$ | $*$ | 1.5 |
| 2 | $3-5$ | $*$ | $\mathbf{7}$ | 4.5 |
| 3 | $6-8$ | $\mathbf{7 , 8}$ | 8 | 7.5 |
| 4 | $9-11$ | 11 | 11 | 10.5 |
| 5 | $12-14$ | $\mathbf{1 2 , 1 4}$ | 12 | 13.5 |
| 6 | $15-17$ | 16 | $\mathbf{1 4}$ | 16.5 |
| 7 | $18-20$ | 18 | $\mathbf{1 6}$ | 19.5 |
| 8 | $21-23$ | $*$ | $\mathbf{1 8}$ | $22.5($ SMSE $=4.5)$ |
| 9 | $24-26$ | $*$ | $*$ | 25.5 |
| 10 | $27-29$ | $*$ | $\mathbf{3 1}$ | 28.5 |
| 11 | $30-32$ | $\mathbf{3 1 , 3 2}(7,8 \mathrm{am})$ | 32 | 31.5 |
| $\ldots$ |  |  |  |  |

- The range is more precisely stated as [low-high), e.g. [21-24): $\geq 21$ and $<24$
- If there is more than 1 observed time per bin, rearrange observed time into neighboring bins: 1 move due to bin 3 and 3 moves due to bin 5
- 4 of 8 observed times are misaligned in the first day: $7,14,16$, and 18
- Misalignment is quantified by the difference between the observed time and the new time midpoint: Time interval plot with SMSE (squared root of mean square error = distance)

## Tinterval Examples: ID = 41 with Interval 2

| Bin \# <br> (bin time) | Bin <br> range | Observed <br> time |
| :---: | :---: | :---: |
| 1 | $0-1$ | $*$ |
| 2 | $2-3$ | $*$ |
| 3 | $4-5$ | $*$ |
| 4 | $6-7$ | 7 |
| 5 | $8-9$ | 8 |
| 6 | $10-11$ | 11 |
| 7 | $12-13$ | 12 |
| 8 | $14-15$ | 14 |
| 9 | $16-17$ | 16 |
| 10 | $18-19$ | 18 |
| 11 | $20-21$ | $*$ |
| 12 | $22-23$ | $*$ |
| 13 | $24-25$ | $*$ |
| 14 | $26-27$ | $*$ |
| 15 | $28-29$ | $*$ |
| 16 | $30-31$ | 31 |
| 17 | $32-33$ | 32 |
| $\ldots$ |  |  |

- Perfect alignment, no need to rearrange observed time

| Bin \# <br> (bin time) | Bin <br> range | Observed <br> time | Observed <br> time rearranged | New time mid <br> point of bin range |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $0-1$ | $*$ | $*$ | $*$ |
| 2 | $2-3$ | $*$ | $*$ | $*$ |
| 3 | $4-5$ | 5 | 5 | 5 |
| 4 | $6-7$ | 7 | 7 | 7 |
| 5 | $8-9$ | $*$ | $\mathbf{1 0}$ | 9 |
| 6 | $10-11$ | $\mathbf{1 0 , 1 1}$ | 11 | 11 |
| 7 | $12-13$ | 13 | 13 | 13 |
| 8 | $14-15$ | $*$ | $*$ | $*$ |
| 9 | $16-17$ | 16 | 16 | 17 |
| 10 | $18-19$ | 18 | 18 | 19 |
| 11 | $20-21$ | $*$ | $*$ | $*$ |
| 12 | $22-23$ | $*$ | $*$ | $*$ |

- 1 misalignment: 10
$\mathrm{ID}=20$, Tinterval $=2$, Day 2

| Bin \# <br> (bin time) | Bin <br> range | Observed <br> time | Observed <br> time rearranged |
| :---: | :---: | :---: | :---: |
| 13 | $24-25$ | $*$ | $*$ |
| 14 | $26-27$ | $*$ | $*$ |
| 15 | $28-29$ | $*$ | $*$ |
| 16 | $30-31$ | 30 | 30 |
| 17 | $32-33$ | 33 | 33 |
| 18 | $34-35$ | $*$ | $\mathbf{3 6}$ |
| 19 | $36-37$ | 36 | $\mathbf{3 8}$ |
| 20 | $38-39$ | $\mathbf{3 8 , 3 9}$ | 39 |
| 21 | $40-41$ | 41 | 41 |
| 22 | $42-43$ | $*$ | $*$ |
| 23 | $44-45$ | $*$ | $*$ |
| 24 | $46-47$ | $*$ | $*$ |

- 2 misalignments. 2 moves.

# Section 3 Descriptive Analyses to Understand the Data TYPE = TWOLEVEL BASIC 

## Data Structure and Analysis Steps

- Data in long format: Time (hours) nested in individuals (ID)

| ID | HOURS | PA |
| :---: | :---: | :---: |
| 1 | 9 | 4 |
| 1 | 10 | 5 |
| 1 | 11 | 5 |
| 1 | 13 | 6 |
| 2 | 9 | 5 |
| 2 | 11 | 7 |
| 3 | $\cdots$ |  |

- Step 1: TYPE = TWOLEVEL BASIC to check histograms, within- and between-level variation and between-level plots (MLR)
- Step 2: TYPE = TWOLEVEL (RANDOM) modeling of variation in mean, variance, and correlation (Bayes), regular twolevel analysis
- Step 3: TYPE = TWOLEVEL (RANDOM) DSEM analysis, bringing in time (Bayes): Univariate
- Step 4: TYPE = TWOLEVEL (RANDOM) DSEM analysis, bringing in time (Bayes): Bivariate
- Step 5: TYPE = CROSSCLASSIFIED (Bayes)

# Step 1: TYPE = TWOLEVEL BASIC for PA, NA, Tired, and Hrs. CLUSTER = ID 

> USEVARIABLES = pa na tired hrs;
> CLUSTER = id;

ANALYSIS:

> TYPE = TWOLEVEL BASIC;

PLOT:
TYPE = PLOT3;

## Step 1: Intraclass Correlations

Estimated Intraclass Correlations for the Y Variables

| Intraclass <br> Variable | Correlation | Intraclass |  | Intraclass |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Variable | Correlation | Variable | Correlation |  |  |
| PA | 0.570 | NA | 0.467 | TIRED | 0.477 |

- $\operatorname{ICC}=\mathrm{V}($ Between $) /(\mathrm{V}($ Between $)+\mathrm{V}($ Within $))$
$=$ Variation across individuals $/$ Total variation
- Variation across individuals is viewed as variation of a random mean, a variable corresponding to individuals' mean across time, that is, variation across individuals in the average level; a trait variable

## Step 1: Histograms for PA, NA, and Tired

$$
\text { PA: } 22 \% \text { ceiling effect. }
$$

NA: $60 \%$ floor effect.

- Max time $=168$ but some beyond (check data)
- Dropoff of people over time
- Few observations late at night and early morning
- Histogram display properties changed from default of 20 to 100 bins

## Step 1: Between-Level Histogram Plot of PA

- Between-level histogram of person average over time
- Less skewed than overall histogram - only $2 \%$ at max value vs $22 \%$

(a) Based on average over time

(b) Based on individual values
- Between-level histogram of averages over time corresponds to the distribution of random intercepts which is assumed to be normal

## Step 1: Between-Level Scatter Plot of PA Mean and Variance

- The variance varies over people and is correlated -0.43 with the mean
- NA scatterplot shows a correlation of 0.65 . Tired shows no correlation

## Section 4 Regular twolevel analysis TYPE = TWOLEVEL (RANDOM)

## Step 2: TWOLEVEL Modeling of PA, NA, and Tired Model 1: Random Mean

- What portion of the total variance is due to variation across individuals in their means across time? What are the predictors of the variation?
- Single outcome, random mean, fixed residual variance:

$$
\begin{equation*}
y_{i t}=\alpha_{i}+\varepsilon_{i t} \tag{1}
\end{equation*}
$$

where $\alpha_{i}$ is the random mean, that is, an average over time that varies across individuals, also seen as a latent trait. The residual $\varepsilon_{i t} \sim N\left(0, \sigma^{2}\right)$ is assumed uncorrelated across individual and time

- The random mean (latent trait) accounts for the correlation across time as expressed by the intraclass correlation

$$
\begin{equation*}
I C C=V(\alpha) / V(y)=V(B) /(V(B)+V(W)) \tag{2}
\end{equation*}
$$

- The ICC is the R-square for the variance of the outcome explained by the random mean, that is, the R -square due to the latent trait
- The random mean plays the role of the intercept growth factor $(\lambda=1)$ in a growth model analyzed in a twolevel, long format

## Step 2 Model 1 for PA: Formula, Diagram, and Input

- $y_{i t}=\alpha_{i}+\varepsilon_{i t}$
- y: observed PA variable (square)
- $\alpha$ : latent PA variable on Between (circle)
- $\varepsilon$ : latent PA variable on Within (circle)
- Diagram drawn like RI-CLPM

USEVARIABLES = pa;
CLUSTER = id;
$!24 * 7=168$ (same as time $>84$ ):
USEOBSERVATIONS =
hrs LE 168 AND id NE 240
AND id NE 249 AND id NE 78
AND id NE 531;
ANALYSIS: $\quad$ TYPE $=$ TWOLEVEL;
ESTIMATOR = BAYES;
BITERATIONS $=(1000)$;
PROCESSORS $=8$;
MODEL: \%WITHIN\%

\%BETWEEN\%
pa(b);
MODEL
CONSTRAINT: NEW(icc);
icc $=b /(b+w)$;
$!$ PA icc estimate $=0.57(.024)$
$!\mathrm{PA}(\mathrm{W})=0.56, \mathrm{PA}(\mathrm{B})=0.75$

## Step 2: TWOLEVEL Modeling of PA, NA, and Tired Model 2: Random Residual Variance

- How much does the residual variance vary across individuals? What are its predictors? What is the correlation between the mean and residual variance?
- Single outcome, random mean, random residual variance:

$$
\begin{equation*}
y_{i t}=\alpha_{i}+\varepsilon_{i t} \tag{3}
\end{equation*}
$$

where $\alpha_{i}$ is the random mean and the residual $\varepsilon_{i t} \sim N\left(0, \sigma_{i}^{2}\right)$, that is, the variance also varies across individuals $\left(\log \sigma_{i}^{2} \sim N\left(\mu, \sigma^{2}\right)\right)$

## Step 2 Model 2 in Formula and Diagram Form

- $y_{i t}=\alpha_{i}+\varepsilon_{i t}, \varepsilon_{i t} \sim N\left(0, \sigma_{i}^{2}\right)$
- y: observed PA variable
- $\alpha$ : latent PA variable on Between
- $\varepsilon$ : latent PA variable on Within
- The random residual variance $\sigma_{i}^{2}$ is represented by logv

## Step 2 Model 2 Input

| MODEL: |  |
| :---: | :---: |
|  | \%WITHIN\% |
|  | $\operatorname{logv} \mid \mathrm{pa} ;!$ Random residual var \%BETWEEN\% |
|  | pa WITH logv; |
|  | [logv] (m); |
|  | $\operatorname{logv}(\mathrm{s}) ;$ |
| MODEL |  |
| CONSTRAINT: |  |
|  | NEW(meanv); $\text { meanv }=\operatorname{EXP}(\mathrm{m}+\mathrm{s} / 2) ;$ |
| OUTPUT: |  |
|  | STANDARDIZED TECH1 |
|  | TECH4 TECH8; |
| PLOT: |  |
|  | TYPE $=$ PLOT $3 ;$ |

## Understanding logv

- Random effects are assumed to be normally distributed which is not suitable for a variance since has a chi-square like distribution and is never negative. Because of this, the log of the variance is instead modeled which is emphasized by calling it logv
- The mean $m$ of the random variance logv can be negative because it is on the $\log$ scale (negative values for residual variances less than 1)
- To get the mean on the regular scale, the logv mean should be exponentiated. The correct exponentiation also involves $s$, the variance of logv: The mean of the variance $=\exp (m+s / 2)$. The theory behind this expression draws on the mean of the log normal distribution.
- The median is $\exp (\mathrm{m})$ and is more useful for the skewed distribution of the variance
- The mean and median of the variance can be expressed in MODEL CONSTRAINT which also gives the confidence interval (Bayes allows a potentially non-symmetric CI)
- A fuller discussion of $\log v$ is presented later in connection with Step 3 Model 2

## Step 2 Model 2 Output Excerpts

|  | Posterior |  |  |  | 95\% C.I. |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Estimate | S.D. | Lower 2.5\% | Upper 2.5\% | Significance |  |
| Within Level <br> Between Level <br> PA WITH |  |  |  |  |  |  |
| LOGV | -0.464 | 0.074 | -0.613 | -0.330 | $*$ |  |
| Means |  |  |  |  |  |  |
| PA | 5.759 | 0.056 | 5.642 | 5.858 | $*$ |  |
| LOGV | -1.025 | 0.074 | -1.168 | -0.880 | $*$ |  |
| Variances | 0.735 | 0.074 | 0.603 | 0.895 | $*$ |  |
| PA |  |  | 0.902 | 1.339 | $*$ |  |
| LOGV | 1.108 | 0.115 |  |  | $*$ |  |
| Pew/Additional <br> MEANCters | 0.626 | 0.058 | 0.527 | 0.760 | $*$ |  |

- The S.D. column corresponds to SE for ML. Estimate/SD is approximately a $z$-score but the CI is a better statistic to report
- The correlation between the random mean PA and the random logv residual variance is -0.52 (the scatterplot correlation was -0.43 )

## Step 2: TWOLEVEL Modeling of PA, NA, and Tired

## Model 3: Random Residual Covariance

 New in Version 8.9- How much do the residual covariances between different variables vary across individuals? What are their predictors?
- Bivariate (or multivariate) outcome, random means, random residual variances and covariance:

$$
\begin{align*}
& y_{i t}=\alpha_{y i}+\varepsilon_{y i},  \tag{4}\\
& z_{i t}=\alpha_{z i}+\varepsilon_{z i t}, \tag{5}
\end{align*}
$$

where the residuals have individually-varying variances, $\varepsilon_{y i t} \sim N\left(0, \sigma_{y i}^{2}\right)$ and $\varepsilon_{z i t} \sim N\left(0, \sigma_{z i}^{2}\right)$, as well as individually-varying covariance $\rho_{i} \sqrt{\sigma_{y i}^{2}} \sqrt{\sigma_{z i}^{2}}$ where $\rho_{i}$ is the correlation (Fisher z-transform of $\rho_{i} \sim N\left(\mu_{r}, \sigma_{r}^{2}\right)$; see Asparouhov \& Muthén (2010). Bayesian analysis using Mplus: Technical implementation. http:
//www.statmodel.com/download/Bayes3.pdf)

## Why Are These Twolevel Models Not Sufficient for Intensive Longitudinal Data?

- What is lacking in the two-level analyses just presented? Model 1 has

$$
\begin{equation*}
y_{i t}=\alpha_{i}+\varepsilon_{i t} \tag{6}
\end{equation*}
$$

- This model accounts for correlation of observations across time using the random mean $\alpha_{i}$ (the latent trait)
- But there is further correlation to take into account: The residuals $\varepsilon_{i t}$ are likely correlated across time due to measurements close in time. For two time points t 1 and $\mathrm{t} 2, \operatorname{Corr}\left(\varepsilon_{i t 1}, \varepsilon_{i t 2}\right)=\rho^{|t 1-t 2|}$, that is, there is a non-zero correlation with size depending on the distance in time
- A common way to model this correlation is the lag-1 auto-correlation model $\varepsilon_{i t}=\beta \varepsilon_{i t-1}+\zeta_{i t}($ see, e.g., Chi \& Reinsel, 1989, JASA)
- Not only does this take into account residual correlation but it also offers substantively interesting modeling - DSEM

## Why Are These Twolevel Models Not Sufficient, Cont'd Relation to DSEM

- Consider the model with auto-correlated residuals,

$$
\begin{align*}
& y_{i t}=\alpha_{i}+\varepsilon_{i t}  \tag{7}\\
& \varepsilon_{i t}=\beta \varepsilon_{i t-1}+\zeta_{i t} \tag{8}
\end{align*}
$$

Inserting (8) into (7) says that

$$
\begin{equation*}
y_{i t}=\alpha_{i}+\beta \varepsilon_{i t-1}+\zeta_{i t} . \tag{9}
\end{equation*}
$$

Equation (7) for t-1 implies that $\varepsilon_{i t-1}=y_{i t-1}-\alpha_{i}$. Inserting this into (9), shows that the model of (7) and (8) implies a within-level part of DSEM with latent variable centering of $y_{i t-1}$,

$$
\begin{align*}
y_{i t} & =\alpha_{i}+\beta\left(y_{i t-1}-\alpha_{i}\right)+\zeta_{i t},  \tag{10}\\
y_{i t}-\alpha_{i} & =\beta\left(y_{i t-1}-\alpha_{i}\right)+\zeta_{i t},  \tag{11}\\
y_{i t}^{W} & =\beta y_{i t-1}^{W}+\zeta_{i t}, \tag{12}
\end{align*}
$$

where $y_{i t}^{W}=\varepsilon_{i t}$.

## Section 5 Two-Level Analysis Bringing Time Into the Model: DSEM for a Single Outcome

## Step 3: Two-Level Modeling Using DSEM Univariate Analysis of PA

- 3 ways to describe the model:
- Model diagram
- Formulas
- Mplus input
- Alternative ways to draw the model diagrams:
- Balance between statistical accuracy and visual simplicity

## Two-Level Modeling Using DSEM: Model Diagram

- Within level: Variation over time (lag-1 shown in figure)
- Between level: Variation over individuals

- The observed variable is decomposed into a Within and a Between part. The Between part is a random intercept varying over persons (also referred to as a latent trait)
- The model diagram is in line with the drawing of the random intercept in Mplus Web Talk 3 and RI-CLPM (Mulder \& Hamaker, 2021)

## Two-Level Modeling Using DSEM: Model Diagram Drawing Conventions

- Only two adjacent time points are shown
- The observed PA variables are shown outside the within and between boxes because they are neither within-only or between-only variables
- The regression coefficients for the observed PA variable on the latent between PA variable and latent within PA variables are all fixed at 1 and the residual is zero (the observed PA is the sum of the two latent PAs reflecting a within-between decomposition of the observed variable)
- The latent within-level PA variables have residuals
- The full within-part of the model is shown only for time point $t$

## Two-Level Modeling Using DSEM: Formulas

- The observed variable $P A_{t}$ is expressed in terms of a random intercept $\alpha$ (labeled $P A$ in the diagram) and the latent-variable centered $P A_{i t-1}$,

$$
\begin{equation*}
P A_{i t}=\alpha_{i}+\beta\left(P A_{i t-1}-\alpha_{i}\right)+\varepsilon_{i t}, \tag{13}
\end{equation*}
$$

where the latent variable centering avoids Nickell's bias (Asparouhov et al., 2018). Hamaker \& Grasman (2015) also discuss centering

- Defining the latent within variable $P A_{i t}^{(W)}=P A_{i t}-\alpha_{i},(13)$ is the same as

$$
\begin{equation*}
P A_{i t}^{(W)}=\beta P A_{i t-1}^{(W)}+\varepsilon_{i t} . \tag{14}
\end{equation*}
$$

## Step 3 Model 1: Mplus Input

- Mplus MODEL command:

$$
\begin{array}{ll}
\text { MODEL: } & \text { \%WITHIN\% } \\
& \text { pa ON pa\& } ; \\
& \text { \%BETWEEN\% } \\
& \text { pa; }
\end{array}
$$

- The within-level slope (AR) and residual variance can be random (individual-specific), adding latent variables to the between level
- Mplus allows a full SEM to be specified on both levels

## Two Alternative Ways to Draw DSEM Model Diagrams

- Mplus User's Guide with random effects marked as filled circles on within and open circles (latent variables) on between

- Hamaker papers/talks emphasizing decomposition into within- and between-level variation

## Diagram Style Chosen for this Web Talk

- Compared to the User's Guide style, there is no filled circle for the random intercept and it is made clear that the regression is for the within variables, implying latent variable centering
- Compared to the Hamaker style, there is no decomposition drawn, the role of the Between PA as a random intercept is emphasized, and there are no (w), (b) superscripts for the variables but instead the variable names match those of the input

# What Defines a DSEM (Time Series) Run in Mplus as Opposed to a Regular Two-Level Analysis? 

- The LAGGED option triggers DSEM (time series analysis) by allowing \&
- The TINTERVAL option can be used only with LAGGED
- TINTERVAL is not necessary for LAGGED
- Not using the TINTERVAL option assumes that time is $1,2,3, \ldots$

## Stationarity

- Stationarity of the time series implies that the mean and variance of the outcome are time invariant
- This is not a modeling limitation but is necessary to match the type of data we are considering
- Without variance stationarity, data would have values that explode over time due to increasingly large variances, that is, data with exponential growth that we typically don't see in our applications
- Consider again the $\operatorname{AR}(1)$ model with the within-level part (dropping the W superscript as in the input)

$$
\begin{equation*}
P A_{i t}=\beta P A_{i t-1}+\varepsilon_{i t}, \tag{15}
\end{equation*}
$$

with the residual variance $V\left(\varepsilon_{i t}\right)=\theta$

- Stationarity requires that $|\beta|<1$ (auto-regression slope less than 1)

## Stationarity vs Non-Stationarity

- What is the variance of $P A_{i t}=\beta P A_{i t-1}+\varepsilon_{i t}$ ? Stationarity implies

$$
\begin{align*}
& V\left(P A_{i t}\right)=\beta^{2} V\left(P A_{i t}\right)+\theta,  \tag{16}\\
& V\left(P A_{i t}\right)=\theta /\left(1-\beta^{2}\right) ;|\beta|<1 \tag{17}
\end{align*}
$$

- The variance stationarity also implies that the unstandardized $\beta$ estimate is the same as the standardized
- Non-stationarity example: Consider 10 consequtive timepoints $1,2,3$, ..., 10 where $\mathrm{V}\left(P A_{i 1}\right)=1$ :

$$
\begin{align*}
& V\left(P A_{i 2}\right)=V\left(\beta P A_{i 1}+\varepsilon_{i 2}\right)=\beta^{2}+\ldots  \tag{18}\\
& V\left(P A_{i 3}\right)=V\left(\beta\left(\beta P A_{i 1}+\varepsilon_{i 2}\right)+\varepsilon_{i 3}\right)=\beta^{4}+\ldots \tag{19}
\end{align*}
$$

- The variance of $P A_{i 10}$ is dominated by the first term $\beta^{2 \times 9}$
- For example, $\beta=1.5$ results in $\mathrm{V}\left(P A_{i 10}\right)=1.5^{18}=1,478$ !
- Non-stationarity of the mean may occur with a trend over time
- A function of time may be used as a covariate, so that RDSEM can be applied with stationarity for the residuals

## Step 3 Model 1: Full Input Including Intraclass Correlation in DSEM

USEVARIABLES = pa;
$!24 * 7=168$ (same as time $>84$ ):
USEOBSERVATIONS $=$ hrs le
168 AND id ne 240
AND id ne 249 AND id ne 78
AND id ne 531;
CLUSTER = ID;
! The LAGGED option
! triggers time series analysis:
LAGGED = pa(1);
! New in version 8.9:
TINTERVAL = hrs (2 time);
ANALYSIS:

$$
\begin{aligned}
& \text { TYPE = TWOLEVEL; } \\
& \text { ESTIMATOR = BAYES; } \\
& \text { BITERATIONS = }(1000) ; \\
& \text { PROCESSORS = } ;
\end{aligned}
$$

! wvar $=r^{*} r^{*}$ wvar + resvar
! which means that:
wvar $=\operatorname{resvar} /\left(1-r^{*} \mathrm{r}\right)$;
icc $=$ bvar/(bvar + wvar);
$!$ icc $=0.56$ (.025)
OUTPUT: STANDARDIZED
TECH1 TECH4 TECH8;
PLOT: $\quad$ TYPE = PLOT3;

- Version 8.9 has changed TINTERVAL to work the same way for TWOLEVEL and CROSSCLASSIFIED DSEM
- Initial missing values for an individual are no longer dropped for TWOLEVEL
- The change causes minimal differences in estimates
- The old approach can be obtained by adding DROP as a third argument in parenthesis for TINTERVAL
- The orginal time variable (hrs in the previous example) is no longer changed by TINTERVAL but a new time variable that the user names is used in the analysis (time in the example) and can be modified in DEFINE
- If no new time variable is named by the user, _BINT is used

## Step 3 Model 1 Output Excerpts

|  | Posterior <br> Estimate | 95\% C.I. |  |  |  |

- Within-level R-square is $1-0.828=0.172$

# Summary of Results for PA Analysis using TINTERVAL = 1, 2, 3 (No Logv) 

$$
\text { Tinterval }=1 \quad \text { Tinterval }=2 \quad \text { Tinterval }=3
$$

| Time interval <br> plot information <br> (metric is hours) |  |  |  |
| :--- | :---: | :---: | :---: |
| Avg. SMSE | 0.500 | 0.832 | 1.872 |
| Max. SMSE | 0.500 | 1.732 | 4.517 |
| Missing data coverage | 0.171 | 0.341 | 0.507 |
| Within Est's | $0.547(.014)$ | $0.414(.014)$ | $0.378(.014)$ |
| AR (1) | $0.410(.010)$ | $0.483(.009)$ | $0.501(.010)$ |
| $\quad$ Resvar | $5.754(.058)$ | $5.756(.058)$ | $5.756(.057)$ |
| Between Est's <br> Mean | $0.734(.073)$ | $0.735(.074)$ | $0.725(.072)$ |
| $\quad$ Var |  |  |  |

- Tinterval = 1 matches the data best but the low coverage (many missing data rows) makes convergence difficult for complex models
- AR(1) values decline with increasing Tinterval but 0.414 is not $0.547 * 0.547$ as expected, suggesting that lag-1 is not sufficient

## Taking a Step Back: $\mathrm{N}=1$ DSEM (Classic Time Series Analysis)

- This model has 3 parameters
- Common multivariate model: Vector auto-regressive (VAR) - like CLPM
- Mplus allows a full SEM to be specified

USEVARIABLES = pa;
USEOBSERVATIONS = id eq 41;
LAGGED = pa(1);
TINTERVAL = hrs (2 time);
ANALYSIS: ESTIMATOR = BAYES;
BITERATIONS $=(1000)$;
PROCESSORS $=8$;
MODEL: pa ON pa\&1;
OUTPUT: STANDARDIZED TECH1
TECH4 TECH8;
PLOT: $\quad$ TYPE = PLOT3;

- A between model is not specified

## $\mathrm{N}=1$ DSEM for PA using ID = 41 (7 days: Tue - Mon)

- Time Series plot:

- X-axis: 79 time points ( 12 occasions per day for 7 days $=\max 84$ )
- 46 of them non-missing: Sample size $=46$

## Output for $\mathrm{N}=1$ DSEM for PA using ID = $41(\mathrm{~N}=46)$

| Posterior <br> Estimate | S.D. | Lower 2.5\% | Upper 2.5\% | Significance |
| :---: | :---: | :---: | :---: | :---: |
| 0.636 | 0.120 | 0.373 | 0.848 | $*$ |
| 2.175 | 0.725 | 0.842 | 3.735 | $*$ |
| 1.071 | 0.274 | 0.705 | 1.757 | $*$ |

- The $\mathrm{N}=1$ model has $P A_{t}=v+\beta P A_{t-1}+\varepsilon_{t}$
- Stationarity implies $E\left(P A_{t}\right)=E\left(P A_{t-1}\right)=\mu$ so that

$$
\begin{align*}
& \mu=v+\beta \mu,  \tag{20}\\
& \mu=v /(1-\beta) . \tag{21}
\end{align*}
$$

- Here, $\mu=5.97$ as shown in TECH4 and RESIDUAL output

## Joint $\mathrm{N}=1$ Analysis of All Individuals

- $\mathrm{N}=1$ analysis of all individuals together can be carried out and estimates averaged using the TYPE $=$ MONTECARLO option of the DATA command in line with User's Guide ex 12.6
- Mplus DSEM input shown at https:
//ellenhamaker.github.io/DSEM-book-chapter/
- See section Empirical Illustration: Part 1 on page 580 of Hamaker, Asparouhov \& Muthén (2023). Dynamic structural equation modeling as a combination of time series modeling, multilevel modeling, and structural equation modeling. Chapter 31 in Handbook of Structural Equation Modeling (2nd edition); Rick H. Hoyle (Ed.); Publisher: Guilford Press.
http://www.statmodel.com/download/
HamakerAsparouhovMuthen21.pdf

Step 3 Model 2: Two-Level Modeling Using DSEM with Random Residual Variance

- The Step 1 TYPE = TWOLEVEL BASIC between-level scatterplot of PA variance and mean showed strong heteroscedastic variance which was correlated with the mean

- The residual variance is interpreted as variation in innovation or random shocks (different reactions to events)
- Random AR(1) can also be added (interpreted as inertia)

```
USEVARIABLES = pa;
! 24*7 = 168 (same as time >84):
USEOBSERVATIONS = hrs LE 168 AND
id NE 240 AND id NE 249 AND id NE }78\mathrm{ AND id NE 531;
CLUSTER = id;
LAGGED = pa(1);
TINTERVAL = hrs (2 time); ! New in version 8.9
```

## Number of Time Points Continued

- Note that the number of time points per individual in a run using the TINTERVAL option includes time points with missing data that was inserted by the TINTERVAL option to synchronize the timing of the measurements
- Consider for example the first individual on the list, $\mathrm{ID}=45$ which has 6 time points -4 of those timepoints have missing data
- To see the number of time points without inserted missing data, do a run without TINTERVAL
- See the data summary for the Step 1 TYPE = TWOLEVEL BASIC run - this shows that ID $=45$ is observed at 2 time points
- It is important to have a sufficient number of time points without missing data when estimating random effects such as regression coefficients because the estimation is based on computing the random effect value for each individual for which " N " is the number of observed timepoints (Asparouhov \& Muthén, 2022, Practical Aspects of Dynamic Structural Equation Models. Technical Report)

## Model Results Without and With Logv

|  | Estimate | Posterior S.D. | One-Tailed P -Value | 95\% C.I. |  |  |

- Jongerling, Laurenceau, Hamaker (2015) in MBR: Bias when ignoring random logv
- $\mathrm{V}(\varepsilon)=\mathrm{v}$, where v has a lognormal distribution ( $>0$ and skewed):

- Because v has a lognormal distribution, $\log \mathrm{v} \sim N\left(\mu, \sigma^{2}\right)$
- This fits with the assumption of normally distributed random effects in Mplus
- The lognormal distribution implies that v has
- Median $=e^{\mu}$
- Mean $=e^{\mu+\sigma^{2} / 2}$
- Variance $=\left(e^{\sigma^{2}}-1\right) e^{2 \mu+\sigma^{2}}$
- Equivalent expression: $\mathrm{V}(\varepsilon)=e^{s}$ (variance $>0$ ) so that $\log \mathrm{V}(\varepsilon)=\mathrm{s}$ has a normal distribution

## Understanding the Random Residual Variance, Continued

- For a skewed distribution like the lognormal for the random residual variance v , quartiles are better summaries than means and variances
- The quartiles can be obtained from the normal logv distribution
- $50 \%$ of the normal distribution lies between the 25 th and 75 th quartiles (0.675 SD from the mean)
- Because the lognormal is a monotonic function of the normal, the quartiles for the residual variance are obtained by exponentiating the normal distribution quartiles

## Understanding the Random Residual Variance Continued

- The quartile estimates and their CIs are obtained by adding MODEL CONSTRAINT with parameter labels from MODEL:

| MODEL: | \%WITHIN\% <br> pa ON pa\&1; <br> $\log \mathrm{v}$ \| pa; <br> \%BETWEEN\% <br> pa WITH logv; <br> [logv] (m); <br> $\operatorname{logv}(\mathrm{s}) ;$ | MODEL CONSTRAINT: | NEW(medianv 25qv 75qv); medianv $=\operatorname{EXP}(\mathrm{m})$; <br> $!25$ th and 75 th quartiles <br> ! based on normal dist of logv: $\begin{aligned} & 25 \mathrm{qv}=\exp (\mathrm{m}-\operatorname{sqrt}(\mathrm{s}) * 0.675) ; \\ & 75 \mathrm{qv}=\exp (\mathrm{m}+\operatorname{sqrt}(\mathrm{s}) * 0.675) ; \end{aligned}$ |
| :---: | :---: | :---: | :---: |

- medianv $=0.313$ (0.023), $\mathrm{CI}=[0.269$ 0.363]
$25 q v=0.154$ (0.013), $\mathrm{CI}=[0.1290 .178]$
$75 q \mathrm{q}=0.635$ (0.052), $\mathrm{CI}=[0.5430 .751$
- The non-random residual variance in Model 1 is 0.483
- The square roots of the quartiles correspond to SDs which can be related to the scale of the variable

## TECH4 Output

- With TYPE = RANDOM, the within-level covariance matrix changes over individuals. TECH4 gives the average over individuals for within (TECH4(CLUSTER) gives cluster-specific results)

| AVERAGE ESTIMATES DERIVED |  |  |  |
| :---: | :---: | :---: | :---: |

- Bayesian autocorrelation plots

## Time Interval Plot for ID = 20 (see Slides 14,72 )

- 12 occasions per day for 2 days $=24$ time points on the x -axis
- The time points on the x -axis represent the values of the TIME variable

- $\operatorname{SMSE}=$ square root of mean square error over all time points (average distance between observed time and new time midpoint)

## Time Series Plot of PA Averages

- Tinterval $=1$ vs 2

- Tinterval $=1$ vs 3

## Time Series Plot of PA for 4 Persons (Tinterval=2)

- Hard to see a pattern from any one individual - DSEM combines information across individuals to get the pattern for the population
- (1) The observed mean for each person
- Average over time for each person
- (2) The estimated between-level mean for each person
- Requires FACTORS = ALL (50) in the PLOT command: The histogram is based on the Bayes estimates of each person's random effect value (factor score) averaged over the 50 draws from the posterior distribution of all parameter estimates (which includes random effects)
- Referred to as B_PA, mean in the Between-level Histograms choice of the Plot menu
- (3) Cluster mean
- For each person, this is the average of the random mean over all iterations during the estimation. Used in the OUTPUT option RESIDUAL(CLUSTER)
- Referred to as PA (estimated cluster mean) in the Between-level Histograms choice of the Plot menu

## Three Kinds of Between-Level Histograms, Cont'd

- Summary of Between-level histogram choices (3rd line):
- (1) PA (average over Within)
- (2) B_PA, mean
- (3) PA (estimated cluster mean)

| Notations: For estimated factor scoces, "mean" and "median" denote the mean and median of the latent vanable distribution. |  |  |
| OK | Concel | Apoy |

## Between-Level Scatterplots

- y-axis: Estimated cluster mean factor scores (2)
- x-axis: Observed average over within (1)

- Some clusters show a discrepancy - most likely due to missing data handled better by the estimated cluster mean (y-axis), drawing on correlated variables in the model
- For more on factor scores, see multiple imputation on slide 95

## Random Effects (Factor Score) Distribution Plots

- Latent variable distribution plots (last line)
- Requires FACTORS = ALL (50) in the PLOT command: The estimated betwen-level mean for each person using several imputations (draws) from the posterior distribution of all parameter estimates (which includes random effects)
- Each person's random effect (or factor) distribution is created by 50 draws after the last Bayes iteration, and the whole distribution is based on the number of people (clusters) times 50. This gives a smoother representation of the histogram (2) of estimated between-level means
- Imputations - also called plausible values - allow uncertainty in the estimates to be accounted for (not just a point estimate for each person)

## Histogram of Estimated Between-Level Mean vs Latent Variable Distribution

- Similar shape (normality is assumed in the model but the posterior updates this prior using the data)

## Mplus Runs

- Mplus outputs and plots
- Step 1: TYPE = TWOLEVEL BASIC
- Step 2: TYPE = TWOLEVEL RANDOM (regular twolevel)
- Step 3, Model 2: Twolevel DSEM with random residual variance
- Plotting for Mac and Linux users: The GH5 file that the PLOT command produces can be used for plots in R:
http://www.statmodel.com/mplus-R/
- New feature: Simple user interface added for R plots with the use of R Shiny

## Section 6 Two-level DSEM and RDSEM Analysis Two Outcomes

# Step 4 Model 1: Bivariate Modeling in DSEM Cross-Lagged Analysis of PA and Tired 

Step 4 Model 1 Stand'd Within Estimates for Cross-Lagged DSEM Analysis of PA and Tired (TINTERVAL = 2)

|  | Posterior | 95\% C.I. |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Estimate | S.D. | Lower 2.5\% | Upper 2.5\% | Significance |

| Tired | 0.786 | 0.013 | 0.760 | 0.811 | $*$ |

- Small effect of Tired $_{t-1} \rightarrow \mathrm{PA}_{t}$. Larger lag0 effect?

## Step 4 Model 1 with All Random Effects and Covariates

## Random Covariance (New in Version 8.9)

- The model allows individually-varying covariance $\rho_{i} \sqrt{\sigma_{P A_{i}}^{2}} \sqrt{\sigma_{\text {Tired }_{i}}^{2}}$ where $\rho_{i}$ is the correlation
- But $\rho_{i}$ is not normally distributed so we transform it
- Fisher z-transform: $z=\frac{1}{2} \ln \left[\left(1+\rho_{i}\right) /\left(1-\rho_{i}\right)\right], z \sim N\left(\mu, \sigma^{2}\right)$
- The reverse formula is $\rho=\left(e^{2 z}-1\right) /\left(e^{2 z}+1\right)$
- The median of the original $\rho$ is obtained as $\left(e^{2 \mu}-1\right) /\left(e^{2 \mu}+1\right)$
- $z$ and $\rho$ are almost identical for $\rho$ values between -0.5 and +0.5

Plot of inverse Fisher-z

## Step 4 Model 1 with All Random Effects: Analysis Strategies

- It is important to have a sufficient number of time points without missing data when estimating random effects such as regression coefficients because the estimation is based on computing the random effect value for each individual for which " N " is the number of observed timepoints - many individuals with few timepoints may complicate the convergence
- Asparouhov \& Muthén (2022). Practical Aspects of Dynamic Structural Equation Models. Technical Report
- Convergence made harder by including individuals that do not vary across time
- Number of random effects should ideally be smaller than the number of time points
- Problems can be avoided by building up the model in steps: Random intercepts only, adding random effects looking for $z$-values $>3$ for their variances, don't correlate the random effects right away

## Number of Time Points for Each Individual (Cluster)

- Is the number of time points sufficient for 9 random effects?
- Tinterval $=2$ with inserted missing data versus the original data

| Size (s) | Cluster ID with Size s |
| :---: | :--- |

## Standardization with TYPE = RANDOM

- Schuurman, Ferrer, de Boer-Sonnenschein, \& Hamaker (2016). How to compare cross-lagged associations in a multilevel autoregressive model. Psychological Methods, 21, 206-221
- Standardization using individual-specific variances for models with random slopes or variances
- Analogous to $\mathrm{N}=1$ analysis
- Mplus computes the standardized values for each individual and presents the average random slope over individuals

## Step 4 Model 1 with All Random Effects: Non-Stationarity Warning

WARNING: PROBLEMS OCCURRED IN SEVERAL ITERATIONS IN THE COMPUTATION OF THE STANDARDIZED ESTIMATES FOR SEVERAL CLUSTERS. THIS IS MOST LIKELY DUE TO AR COEFFICIENTS GREATER THAN 1 OR PARAMETERS GIVING NON-STATIONARY MODELS. SUCH POSTERIOR DRAWS ARE REMOVED. THE FOLLOWING CLUSTERS HAD SUCH PROBLEMS:

$$
\begin{aligned}
& 4523819719631957216145641535727617610729254549204224 \\
& 20516520043340637131413320347722151383385277175351122 \\
& 216055449503556715604454289244231746336145420234552 \\
& 2603092633945423233837343848566211152480557380499419 \\
& 1018525818837422038846520356140134131207279144302392 \\
& 514148327443570448393398286403407414304394404127100 \\
& 22522846232846816324350865518521
\end{aligned}
$$

- Far fewer clusters are mentioned when the auto-correlations are not random

## Non-Stationarity Warning Continued

- FAQ: Standardized coefficients in DSEM/RDSEM http:
//www. statmodel.com/download/FAQ-DSEMStand.pdf
- Message can typically be ignored (Mplus handles it optimally)
- Typical reasons:
- Major cause is random auto-correlations where in some iterations for some individuals, some part of the posterior distribution is $>1$ so that variances are negative under stationarity assumption which means that standardization cannot be done
- Small sample size or small number of timepoints for many individuals
- Further information about causes can be obtained by
- $\mathrm{N}=1$ analyses
- Examining factor scores to find clusters with large auto-correlations (see later slide)

## Step 4 Model 1 with All Random Effects

- Unstandardized between-level estimates

|  | Posterior | 95\% C.I. |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |

- STD standardization has no effect here due to no latent variables, making the results comparable to the unstandardized between-level estimates
- Note that LOGV entries are on the variance scale (so pos. values; no exp needed)
- SE's of these cluster averages decrease as a function of cluster size
- For significance testing of a random slope mean, the unstandardized mean should be used, not the cluster-averaged standardized slope

## Step 4 Model 1 Regression on Covariates

- Unstandardized between-level estimates

## 3 Ways to Examine the Individuals' Values of the Random Effects (Factor Score Values)

- (1) To view the factor score distribution:
- PLOT command using FACTORS = ALL (50), or FACTORS = list, and using the Latent variable distribution plot
- (2) To get factor score mean, median, variance and percentile summaries saved in a file together with the rest of the data for a follow-up analysis:
- SAVEDATA command using SAVE = FSCORES (50 10), where 10 refers to thinning
- (3) To get multiple imputations of factors scores and save all the between-level information per imputation to be subsequently analyzed in a single-level model using TYPE $=$ IMPUTATION in the DATA command:
- SAVEDATA command using SAVE = FSCORES (200), FACTORS = list, and FILE = name imp*.dat
- Asparouhov \& Muthén (2010). Plausible values for latent variables using Mplus. Technical Report http: //www.statmodel.com/download/Plausible.pdf

## Example of (2): Saving Factor Score Summaries

- SAVEDATA: SAVE = FSCORES(50 10); FILE = fscoresM1.dat;

| PA | F10.3 | STP Standard Deviation | F10.3 |
| :---: | :---: | :---: | :---: |

| STP Median | F10.3 | ID | I4 |

## Follow-Up Two-Level Basic Analysis of the Saved Factor Scored Summaries

- Between-level scatterplot of PA Auto-Correlation’s 97.5 Percentile vs PA Average

- Pointing at top left individual (cluster) with the highest percentile value ( $y$-axis) of 0.97 shows that it is ID $=414$
- Unusual individual with a very low PA average - outlier to be deleted?

# Step 4 Model 2: Adding a Lag0 Effect of $\operatorname{Tired}_{t} \rightarrow \mathrm{PA}_{t}$ to the Cross-Lagged Analysis of PA and Tired 

MODEL:
\%WITHIN\%
pa ON pa\&1 tired tired\&1;
tired ON tired\&1 pa\&1;

# Model 2 Standard'd Estimates for Cross-Lagged Analysis of PA and Tired Without and With Lag0 Effect of Tired ${ }_{t} \rightarrow \mathrm{PA}_{t}$ 

|  |  | Posterior |  | $95 \%$ C.I. |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Estimate | S.D. | Lower 2.5\% | Upper 2.5\% | Significance |
| Only Lag1 effect of Tired |  |  |  |  |  |
| Within Level |  |  |  |  |  |
| PA ON |  |  |  |  |  |
| PA\&1 | 0.398 | 0.015 | 0.369 | 0.426 | $*$ |
| Tired\&1 | $\mathbf{- 0 . 0 8 4}$ | 0.016 | -0.114 | -0.052 | $*$ |
|  |  | Lag0 and Lag1 effect of Tired |  |  |  |
| Within Level |  |  |  |  |  |
| PA ON |  |  |  |  |  |
| PA\&1 | 0.396 | 0.015 | 0.366 | 0.423 | $*$ |
| Tired | $\mathbf{- 0 . 1 9 3}$ | 0.014 | -0.220 | -0.165 | $*$ |
| Tired\&1 | -0.005 | 0.018 | -0.029 | 0.039 |  |

## Step 4 Model 3: RDSEM

- Within-level part of the model:

\%WITHIN\%
PA ON TIRED;
PA ON PA\&1;
TIRED ON TIRED\&1;

\%WITHIN\%
PA ON TIRED;
$\mathrm{PA}^{\wedge} \mathrm{ON} \mathrm{PA}^{\wedge} 1$;
TIRED^ ${ }^{\wedge}$ N TIRED ${ }^{\wedge}$;
- RDSEM is like regular twolevel analysis regressing PA on Tired: No lagged effects but instead auto-correlated residuals
- RDSEM $=$ DSEM if no covariates (Tired in this case)

## DSEM vs RDSEM Continued

- Apart from Tired $_{t} \rightarrow P A_{t}$, the two models have different implications:
- DSEM: Indirect influence Tired $_{t-1} \rightarrow P A_{t-1} \rightarrow P A_{t}$
- RDSEM: Only the residual of $P A_{t-1}$ influences $P A_{t}$
- The 2 models give different estimates of the regression of $P A_{t}$ on Tired $_{t}$ - small difference in this example but this is not always the case
- Asparouhov \& Muthén (2019). Comparison of models for the analysis of intensive longitudinal data. SEM journal. Tables 6 and 7
- RDSEM can be used to study the relationship between two outcomes controlling for covariates, e.g., a trend such as daily cycles

## RDSEM Analysis with a Random Slope Regressed on Between-Level Covariates

## Section 7 Categorical Outcome

## Categorical Outcome: Negative Affect

- $60 \%$ at the lowest value of NA: Treating the variable as continuous leads to model misspecification of linear models such as DSEM typically causing underestimated regression slopes
- Dichotomize the variable (trichotomize?). Censored? Two-part?
- Asparouhov et al. (2018). Dynamic structural equation models. SEM
- Normally distributed latent response variable Y* underlying the categorical observed variable Y is assumed with the regular linear DSEM applied to $\mathrm{Y}^{*}$ (see also Mplus Web Talk 4, Part 2)
- Nominal and count not available for DSEM

## Binary Outcome: Input for Dichotomized NA Individuals not Changing over Time Deleted

```

## Section 8 Cross-Classified Analysis

## Cross-Classified Analysis: Looking for Trends Over Time

- Time series plots of PA and Tired averages in the sample:

- The sample averages have varying precision over time
- can we get a time series plot for model-estimated values?
- Yes, by cross-classified analysis

## Cross-Classified Time Series Analysis $(N>1)$

- Two between-level cluster variables: person crossed with time (one observation for a given person at a given time point)
- Generalization of the two-level model providing more flexibility: random effects can vary across not only persons but also time
- Consider the two-level model with a random intercept/mean:

$$
\begin{equation*}
y_{i t}=\underbrace{\alpha+\alpha_{i}}_{\text {Between person }}+\underbrace{\beta y_{w, i t-1}+\varepsilon_{i t}}_{\text {Within person }} . \tag{22}
\end{equation*}
$$

The corresponding cross-classified model is:

$$
\begin{equation*}
y_{i t}=\underbrace{\alpha+\alpha_{i}}_{\text {Between person }}+\underbrace{\alpha_{t}}_{\text {Between time }}+\underbrace{\beta y_{w, i t-1}+\varepsilon_{i t}}_{\text {Within person }} \tag{23}
\end{equation*}
$$

- $\alpha_{i}$ and $\alpha_{t}$ are normally distributed with zero means
- The Bayes MCMC algorithm is more complex and slower

## Step 5: Cross-Classified Analysis of PA and Tired Mplus Input

MODEL:

USEVARIABLES = pa tired;
LAGGED = pa(1) tired(1);
TINTERVAL = hrs(2 time);
CLUSTER = id time;
ANALYSIS:
TYPE $=$ CROSSCLASSIFIED;
ESTIMATOR = BAYES;

## Time Series Plot of Estimated Random Effects (Factor Scores) for PA and Tired

- Cross-classified analysis with CLUSTER = id time
- The two between levels are referred to as level2a for time and level2b for id
- The acronym B2a is used for the between-time level factor score to be plotted
- Plotting:
- PLOT option: FACTORS=ALL(50)
- Plot menu option: Time series plots (sample value, ACF, PACF, estimated factor score)
- B2a_PA, mean
- B2a_Tired, mean

## Time Series Plot for PA and Tired Factor Scores, Tue-Mon

- How do you model these trends/cycles? Future DSEM web talk
- See also Short Course Topic 13, Part 8 with a heart rate example
- Plots for step 5 cross-classified analysis of PA and Tired
- Time series plot for estimated factor scores: B2a_PA, B2a_Tired
- Right-click options: Mean line, time lines
- More plot options discussed in future web talk
- Loop insert (cycles, weekday effects)

## Section 9 How Large do N and T Have to Be? Monte Carlo Simulations

## How Large do N and T Have to Be? Checklist

- Do you have enough timepoints? Recommendations:
- At least 15-20 (if not, do single-level, wide analysis)
- At least 25 for good performance with random slopes and var's
- At least 50 for $\operatorname{good} \mathrm{N}=1$ performance
- Do enough individuals have enough timepoints without missing?
- If not, random slope and variance estimation can be problematic
- Does your outcome have variation across time?
- Delete individuals with no variation
- Do you have enough individuals for random effects modeling on between?
- A minimum of 50 recommended but many more may be needed for between-level variances ( 500 in the simulation below)
- Does your outcome have a strong trend that should be modeled?
- If yes, use RDSEM with a function of time as covariate
- Do your own Monte Carlo simulation

## How Large do N and T Have to Be? Monte Carlo

- Schultzberg \& Muthén (2018). Number of subjects and time points needed for multilevel time series analysis: A simulation study of dynamic structural equation modeling. Structural Equation Modeling
- 9 univariate DSEM models with varying complexity
- Example: A univariate model with random intercept, random auto-regression and random residual variance needed $\mathrm{T}=25$ for $\mathrm{N}=150$ and $\mathrm{T}=50$ for $\mathrm{N}=100$
- "What is worse, having a lower N or a lower T? Can large N compensate for small T better than large T can compensate for small N ? The answer seems to be clear: Large N is better. That is, large N seems able to compensate for small T , better than large T can compensate for small N . - With that said, the random AR and residual variance do need fairly large T to be well estimated. If AR or residual variance is of substantive interest rather than just a heterogeneity feature to control for, many repeated measures will be needed." (p. 511)
- Current study: $\mathrm{N}=240$ and average $\mathrm{T}=24$, so sufficient for a univariate model - is it sufficient for a multivariate model?

## Monte Carlo Simulations

- Parameter values obtained via SVALUES in the real-data run based on Step 4 Model 2 (lag-0 effect of Tired on PA)
- $\mathrm{N}=250, \mathrm{~T}=25$

MONTECARLO:

```
NAMES = pa tired;
NOBSERVATIONS = 6250;
NREPS = 500;
CSIZES = 250(25);
NCSIZES = 1;
LAGGED = pa(1) tired(1);
! See UG ex12.6:
! REPSAVE = ALL;
! SAVE = step4Model2rep*.dat;
! Or for one replication:
! SAVE = step4Model2.dat;
```

ANALYSIS:

$$
\begin{aligned}
& \text { TYPE = TWOLEVEL; } \\
& \text { ESTIMATOR = BAYES; } \\
& \text { BITERATIONS = }(1000) ; \\
& \text { PROCESSORS = 8; }
\end{aligned}
$$

MODEL
POPULATION: \%WITHIN\%
pa ON pa\&1*0.39510;
pa ON tired*-0.11099;
pa ON tired\& $1 * 0.00309$;
tired ON tired\& $1 * 0.46071$;
tired ON pa\& $1^{*}-0.01164$;

tired*1.39159;
\%BETWEEN\%
pa WITH tired*-0.54293;
[ pa*5.74638];
[ tired*3.39010 ];
pa*0.73492;
tired*1.48918;
MODEL:
! Copy MODEL POPULATION

## Monte Carlo Results Summary

- $\mathrm{N}=250, \mathrm{~T}=25$ : Excellent results (estimates, SEs, coverage)
- $\mathrm{N}=250, \mathrm{~T}=15$ : Good results (a bit low coverage for Tired AR)
- $\mathrm{N}=250, \mathrm{~T}=10$ : Not acceptable results
- A more realistic analysis is obtained with varying cluster sizes (individuals with different number of time points)
- The real data has max 84 time points and average number of time points $=24$
- An approximation to this is obtained by e.g. the 5 cluster sizes: CSIZES $=10(5) 65(15) 100(25) 65(50) 10(80)$;
- 10 clusters of size 5,65 clusters of size 15 , etc for a total of 250 clusters (N)
- Still excellent results

## Monte Carlo Simulations with Random Slopes

- Parameter values obtained via SVALUES in the real-data run based on Step 4 Model 1 with added random slopes, random variances, and random covariance (total of 9 random effects)
- $\mathrm{N}=250$ with the 5 cluster sizes used on the previous slide
- Good results, except between-level variances have somewhat biased estimates (overestimated) and SEs $-\mathrm{N} \geq 500$ is needed
- New in version 8.9 (message shown in TECH9):

## 351 CLUSTERS WERE REMOVED BECAUSE THEIR GENERATED RANDOM EFFECTS PRODUCED NON-STATIONARY TIME SERIES OR NON-POSITIVE DEFINITE COVARIANCE MATRICES.

- With random slopes, variances, and covariances, non-stationarity is likely for some clusters in some replications
- In the past, such replications have been deleted leading to a low percentage of reported replications - now the cluster is thrown out but the replication kept
- 351 clusters is less than $1 \%$ of the $250 * 500$ of the generated clusters

## CrossClassified Monte Carlo

MONTECARLO:

$$
\begin{aligned}
& \text { NAMES = pa tired; } \\
& \text { NOBSERVATIONS = 21000; } \\
& \text { NREPS = } 100 ; \\
& \text { CSIZES = 10[5(1)] } \mathbf{6 5 [ 1 5 ( 1 ) ]} \\
& \mathbf{1 0 0 [ 2 5 ( 1 ) ] ~ 6 5 [ 5 0 ( 1 ) ] ~ 1 0 [ 8 0 ( 1 ) ] ; ~} \\
& \text { NCSIZES = 5[5]; } \\
& \text { LAGGED = pa(1) tired(1); }
\end{aligned}
$$

ANALYSIS:

$$
\begin{aligned}
& \text { TYPE = CROSSCLASSIFIED; } \\
& \text { ESTIMATOR = BAYES; } \\
& \text { BITERATIONS = }(1000) ; \\
& \text { PROCESSORS=8; }
\end{aligned}
$$

- In the SVALUES from the real-data run, \%Between time\% has to be replaced by \%Between level $2 \mathrm{a} \%$ and $\%$ Between $\mathrm{id} \%$ has to be replaced by $\%$ Between level2b\%
